

CSE 127: Computer Security

ROP, heap attacks, CFI, integer overflows

Deian Stefan

Some slides adopted from Nadia Heninger, Kirill Levchenko, Stefan Savage, Stephen Checkoway, Hovav Shacham, Raluca Popal, and David Wagner

Today

- Advanced modern attack techniques
 - ROP
 - Heap-based attacks
- Control flow integrity
- Integer overflow attacks

**Employees must
wash hands before
returning to libc**

What if there is no code that does what we want?

Return-Oriented Programming

is A lot like a ransom
note, BUT instead of cutting
cut Letters from magazines,
YOU ARE cutting out
instructions from text
segments

ret Steve Checkoway
ret Dino Dai Zovi

The Geometry of Innocent Flesh on the Bone: Return-into-libc without Function Calls (on the x86)

Hovav Shacham*
hovav@cs.ucsd.edu

Return-Oriented Programming

Return-Oriented Programming

- Idea: make shellcode out of existing code
- Gadgets: code sequences ending in ret instruction
 - Overwrite saved %eip on stack to pointer to first gadget, then second gadget, etc.

Return-Oriented Programming

- Idea: make shellcode out of existing code
- Gadgets: code sequences ending in ret instruction
 - Overwrite saved %eip on stack to pointer to first gadget, then second gadget, etc.
- Where do you often find ret instructions?

Return-Oriented Programming

- Idea: make shellcode out of existing code
- Gadgets: code sequences ending in ret instruction
 - Overwrite saved %eip on stack to pointer to first gadget, then second gadget, etc.
- Where do you often find ret instructions?
 - End of function (inserted by compiler)

Return-Oriented Programming

- Idea: make shellcode out of existing code
- Gadgets: code sequences ending in ret instruction
 - Overwrite saved %eip on stack to pointer to first gadget, then second gadget, etc.
- Where do you often find ret instructions?
 - End of function (inserted by compiler)
 - Any sequence of executable memory ending in 0xc3

`%edx = 0xdeadbeef`

relevant code:

`0x08049b62: nop`

`0x08049b63: ret`

`...`

`0x08049bbc: pop %edx`

`%eip → 0x08049bbd: ret`

What does this gadget do?

`%edx = v1`

`mov v1, %edx`

How do you use this as an attacker?

- Overflow the stack with values and addresses to such gadgets to express your program
- E.g., if shellcode needs to write a value to %edx, use the previous gadget

What does this gadget do?

`mem[v2] = v1`

```
mov v2, %ebx
mov v1, %(%ebx)
```

Can express arbitrary programs

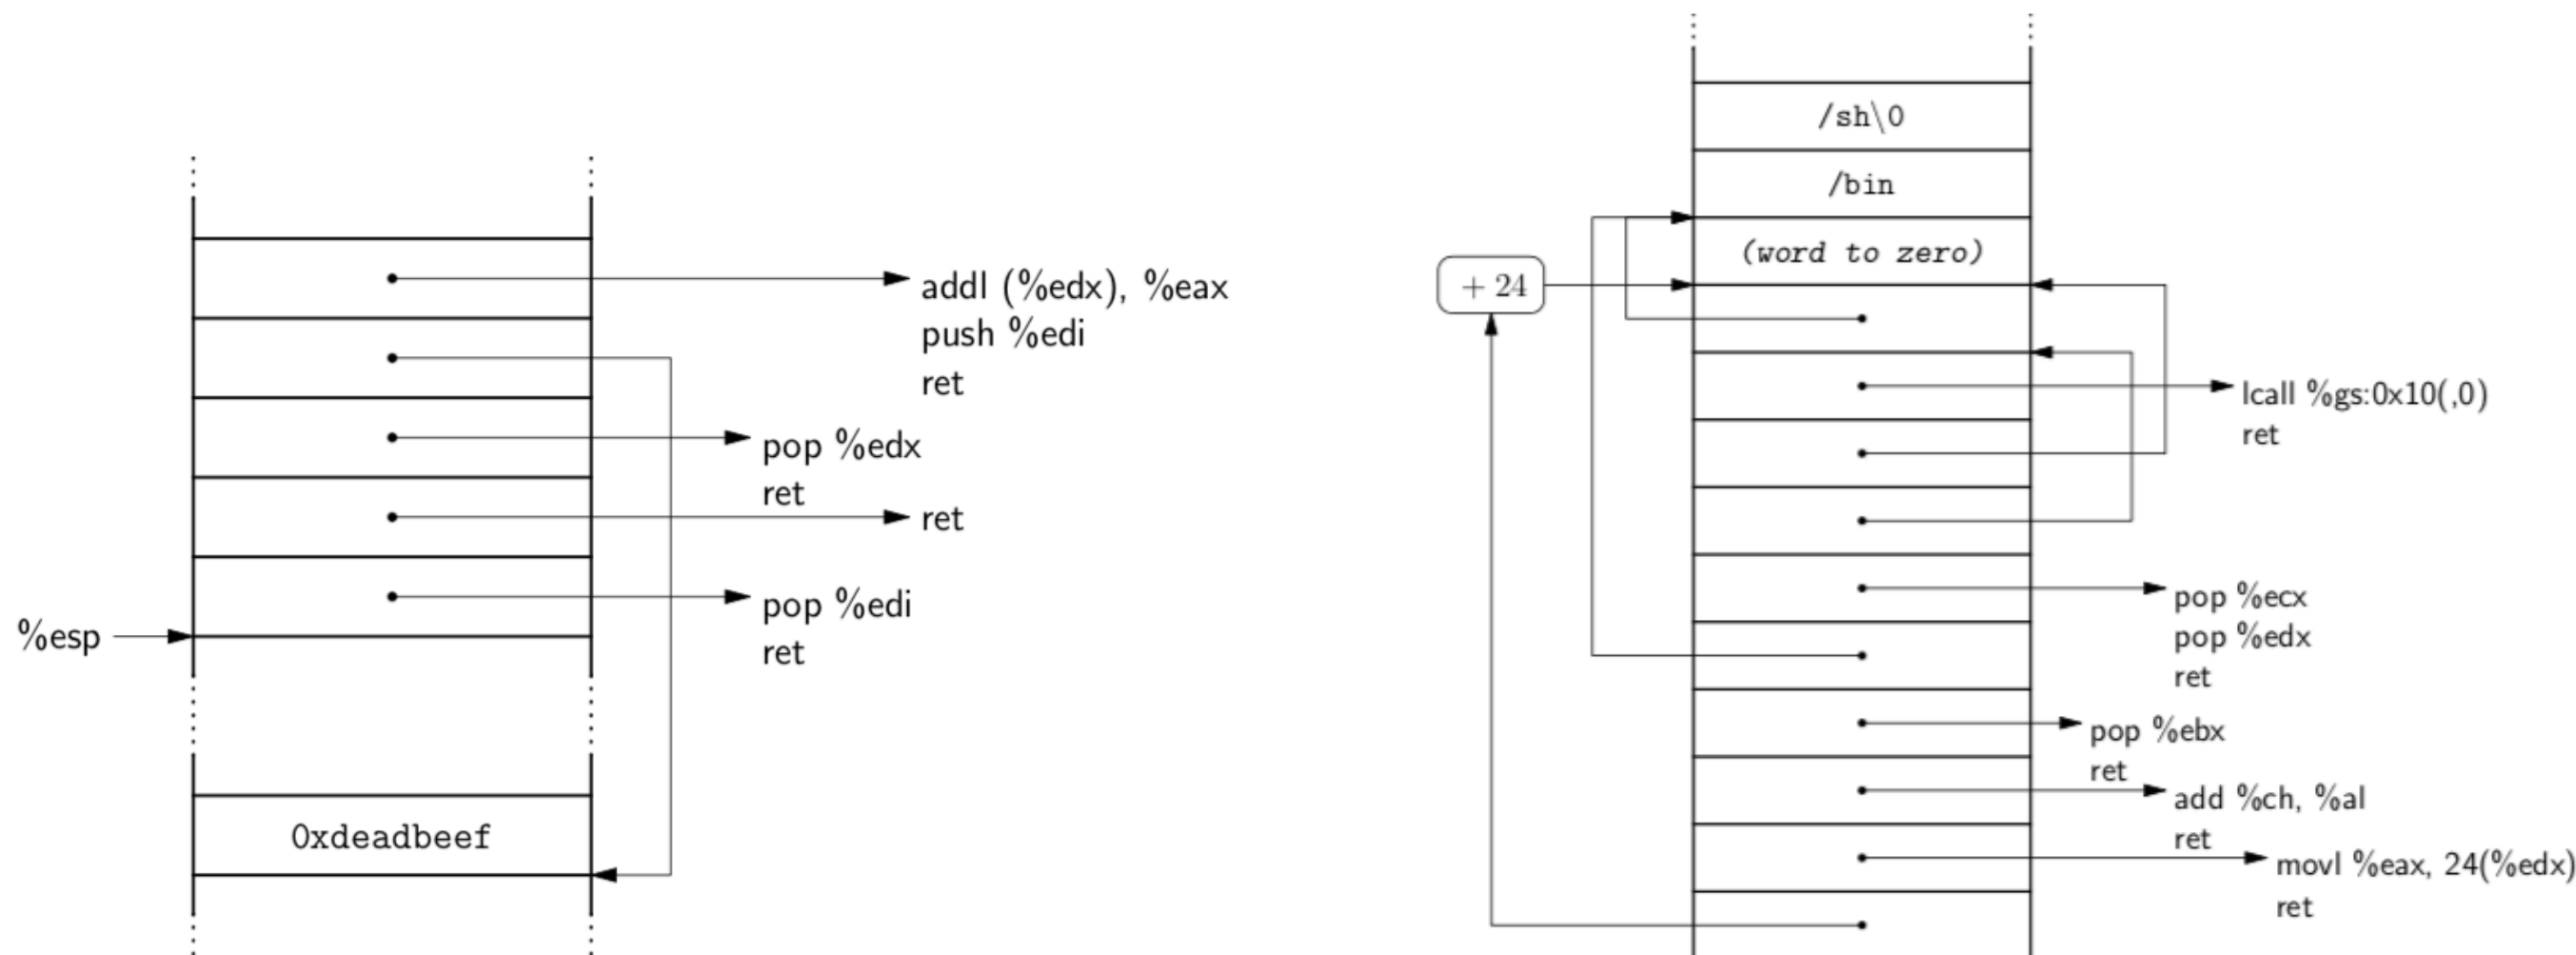

Figure 5: Simple add into %eax.

Figure 10: An infinite loop by means of an unconditional jump.

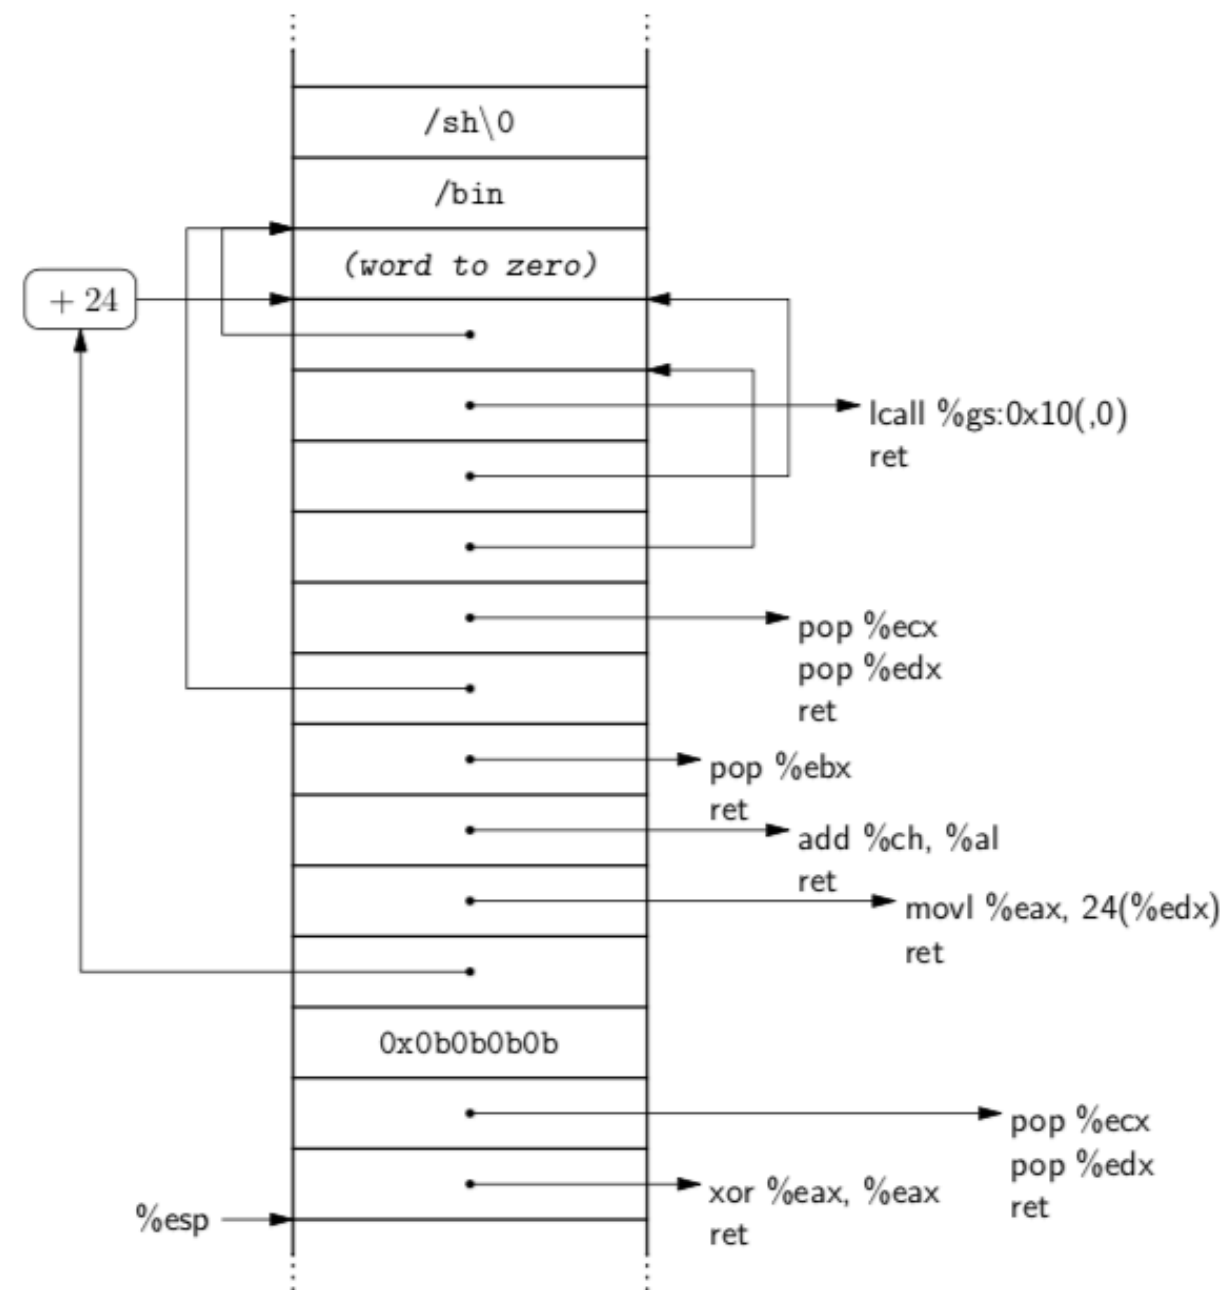

Figure 16: Shellcode.

Can find gadgets automatically

Hacking Blind

Andrea Bittau, Adam Belay, Ali Mashtizadeh, David Mazières, Dan Boneh

Stanford University

Ropper - rop gadget finder and binary information tool

You can use ropper to look at information about files in different file formats and you can find ROP and JOP gadgets to build chains for different architectures. Ropper supports ELF, MachO and the PE file format. Other files can be opened in RAW format. The following architectures are supported:

- x86 / x86_64
- Mips / Mips64
- ARM (also Thumb Mode)/ ARM64
- PowerPC / PowerPC64

Return-Oriented Programming

not even really about “returns”...

Today

- Advanced modern attack techniques
 - ROP
 - Heap-based attacks
- Control flow integrity
- Integer overflow attacks

Handling heap-allocated memory can be just as error-prone as the stack

- We may:
 - Write/read memory we shouldn't have access to
 - Forget to free memory
 - Free already freed objects
 - Use pointers that point to freed object
- What if the attacker can cause the program to use freed objects?

Heap corruption

- Can bypass security checks (data-only attacks)
 - E.g., isAuthenticated, buffer_size, isAdmin, etc.
- Can overwrite function pointers
 - Direct transfer of control when function is called
 - C++ virtual tables are especially good targets

vtables

- Each object contains pointer to vtable
- Array of function pointers
 - one entry per function
- Call looks up entry in vtable

Q: What does `bar()` compile to?

A: `*(obj->vtable[0])(obj)`

```
class Base {
    public: virtual void foo() {
        cout << "Hi\n";
    }
};

class Derived: public Base {
    public: void foo() {cout << "Bye\n";}
};

void bar(Base* obj) { obj->foo(); }

int main(int argc, char* argv[])
{
    Base *b = new Base();
    Derived *d = new Derived();

    bar(b);
    bar(d);
}
```

What does a use after free (UAF) attack look like?

Victim: Free object: `free(obj);`

Attacker: Overwrite the vtable of the object so entry (e.g., `obj->vtable[0]`) points to attacker gadget

Victim: Use dangling pointer: `obj->foo()`

Today

- Advanced modern attack techniques
 - ROP
 - Heap-based attacks
- Control flow integrity
- Integer overflow attacks

Control Flow Integrity

- In almost all the attacks we looked at, the attacker is overwriting jump targets that are in memory (return addresses on the stack and function pointers on the stack/heap)
- **Idea:** don't try to stop the memory writes.
Instead: restrict control flow to legitimate paths
 - I.e., ensure that jumps, calls, and returns can only go to allowed target destinations

Restrict indirect transfers of control

Restrict indirect transfers of control

- Why do we not need to do anything about direct transfer of control flow (i.e., direct jumps/calls)?

Restrict indirect transfers of control

- Why do we not need to do anything about direct transfer of control flow (i.e., direct jumps/calls)?
 - Address is hard-coded in instruction. Not under attacker control

Restrict indirect transfers of control

Restrict indirect transfers of control

- What are the ways to transfer control indirectly?

Restrict indirect transfers of control

- What are the ways to transfer control indirectly?
- Forward path: jumping to (or calling function at) an address in register or memory
 - E.g., qsort, interrupt handlers, virtual calls, etc.
- Reverse path: returning from function (uses address on stack)

What's a legitimate target?

Look at the program control-flow graph (CFG)!

```
void sort2(int a[],int b[], int len {  
    sort(a, len, lt);  
    sort(b, len, gt);  
}
```

```
bool lt(int x, int y) {  
    return x < y;  
}
```

```
bool gt(int x, int y) {  
    return x > y;  
}
```

What's a legitimate target?

Look at the program control-flow graph (CFG)!

```
void sort2(int a[],int b[], int len {  
    sort(a, len, lt);  
    sort(b, len, gt);  
}
```

```
bool lt(int x, int y) {  
    return x < y;  
}
```

```
bool gt(int x, int y) {  
    return x > y;  
}
```

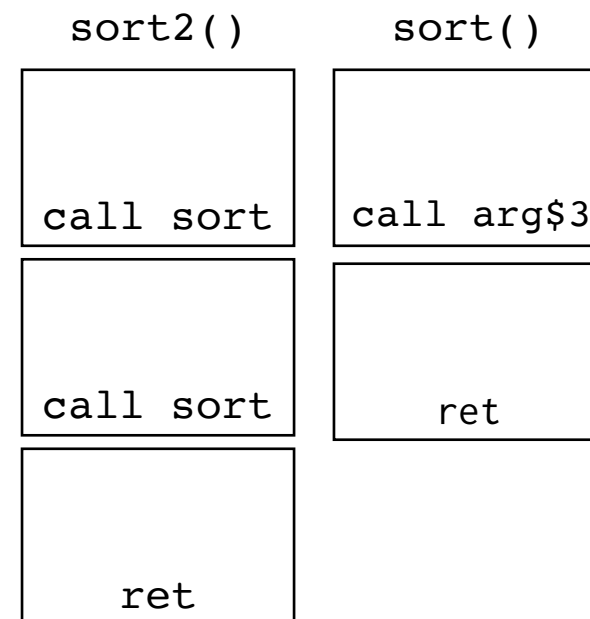

What's a legitimate target?

Look at the program control-flow graph (CFG)!

```
void sort2(int a[],int b[], int len {  
    sort(a, len, lt);  
    sort(b, len, gt);  
}
```

```
bool lt(int x, int y) {  
    return x < y;  
}
```

```
bool gt(int x, int y) {  
    return x > y;  
}
```

What's a legitimate target?

How do we restrict jumps to CFG?

- Assign labels to all indirect jumps and their targets
- Before taking an indirect jump, validate that target label matches jump site
 - Like stack canaries, but for control flow target
- Need hardware support
 - Otherwise trade off precision for performance

Fine grained CFI (Abadi et al.)

- Statically compute CFG
- Dynamically ensure program never deviates
 - Assign label to each target of indirect transfer
 - Instrument indirect transfers to compare label of destination with the expected label to ensure it's valid

Fine grained CFI (Abadi et al.)

```
void sort2(int a[],int b[], int len {  
    sort(a, len, lt);  
    sort(b, len, gt);  
}
```

```
bool lt(int x, int y) {  
    return x < y;  
}
```

Coarse-grained CFI (bin-CFI)

- Label for destination of indirect calls
 - Make sure that every indirect call lands on function entry
- Label for destination of rets and indirect jumps
 - Make sure every indirect jump lands at start of BB

Coarse-grained CFI (bin-CFI)

- Label for destination of indirect calls
 - Make sure that every indirect call lands on function entry
- Label for destination of rets and indirect jumps
 - Make sure every indirect jump lands at start of BB

How else can you choose labels?

$$\frac{tf = t_1^* \rightarrow t_2^* \quad C_{\text{table}} = n}{C \vdash \mathbf{call_indirect} \, tf : t_1^* \, \text{i32} \rightarrow t_2^*}$$

$s; (\text{i32.const } j) \, \mathbf{call_indirect} \, tf \quad \hookrightarrow_i \quad \mathbf{call} \, s_{\text{tab}}(i, j)$
 $s; (\text{i32.const } j) \, \mathbf{call_indirect} \, tf \quad \hookrightarrow_i \quad \mathbf{trap}$

if $s_{\text{tab}}(i, j)_{\text{code}} = (\mathbf{func} \, tf \, \mathbf{local} \, t^* \, e^*)$
 otherwise

How else can you choose labels?

WebAssembly does it by
looking at function type

$$\frac{tf = t_1^* \rightarrow t_2^* \quad C_{\text{table}} = n}{C \vdash \text{call_indirect } tf : t_1^* \text{ i32} \rightarrow t_2^*}$$

$s; (\text{i32.const } j) \text{ call_indirect } tf \hookrightarrow_i \text{call } s_{\text{tab}}(i, j)$
 $s; (\text{i32.const } j) \text{ call_indirect } tf \hookrightarrow_i \text{trap}$

if $s_{\text{tab}}(i, j)_{\text{code}} = (\text{func } tf \text{ local } t^* e^*)$
 otherwise

CFI limitations

- Overhead
 - Runtime: every indirect branch instruction
 - Size: code before indirect branch + encode label at destination
- Scope
 - CFI does not protect against data-only attacks
 - Needs reliable W^X

How can you defeat CFI?

- Imprecision can allow for control-flow hijacking
 - Can jump to functions that have same label
 - E.g., even if we use Wasm's labels `int system(char*)` and `int myFunc(char*)` share the same label
 - Can return to many more sites
 - But, real way to do backward edge CFI is to use a shadow stack. (This is actually great!)

Today

- Advanced modern attack techniques
 - ROP
 - Heap-based attacks
- Control flow integrity
- Integer overflow attacks

What's wrong with this program?

```
void vulnerable(int len, char *data) {  
    char buf[64];  
    if (len > 64)  
        return;  
    memcpy(buf, data, len);  
}
```

What's wrong with this program?

```
void vulnerable(int len, char *data) {  
    char buf[64];  
    if (len > 64)  
        return;  
    memcpy(buf, data, len);  
}
```

```

Is this program safe?

```
void f(size_t len, char *data) {  
    char *buf = malloc(len+2);  
    if (buf == NULL)  
        return;  
    memcpy(buf, data, len);  
    buf[len] = '\n';  
    buf[len+1] = '\0';  
}
```

Is this program safe?

No!

```
void f(size_t len = 0xffffffff, char *data) {  
    char *buf = malloc(len+2 = 0x000000001);  
    if (buf == NULL)  
        return;  
    memcpy(buf, data, len = 0xffffffff);  
    buf[len] = '\n';  
    buf[len+1] = '\0';  
}
```

Issue 952406: Security: Possible OOB related to chrome_sqlite3_malloc

Reported by [mlfbr...@stanford.edu](#) on Fri, Apr 12, 2019, 1:59 PM PDT

Code

VULNERABILITY DETAILS

Possible OOB with chrome_sqlite3_malloc

REPRODUCTION CASE

There's a pattern of using sqlite malloc functions that call chrome_sqlite3_malloc in combination with traditional memory operations (e.g., memcpy). There may be invariants that make this ok, or a principle here that I am not aware of. Thanks for your time.

chrome_sqlite3_malloc takes an `int` size argument, while `memcpy` takes a `size_t` size argument. On x86-64 this means that chrome_sqlite3_malloc's size argument is width 32, while memcpy's is width 64. This can lead to potentially concerning wrapping behavior for extreme allocation sizes (depending on the compiler, optimizations, etc).

For example:

Function fts3UpdateDocTotals

(https://cs.chromium.org/chromium/src/third_party/sqlite/patched/ext/fts3/fts3_write.c?type=cs&q=fts3UpdateDocTotals&q=0&l=3399)

```
(1) a = sqlite3_malloc( (sizeof(u32)+10)*nStat );
```

(https://cs.chromium.org/chromium/src/third_party/sqlite/patched/ext/fts3/fts3_write.c?type=cs&q=fts3UpdateDocTotals&q=0&l=3416)

...

```
(2) memset(a, 0, sizeof(u32)*(nStat));
```

(https://cs.chromium.org/chromium/src/third_party/sqlite/patched/ext/fts3/fts3_write.c?type=cs&q=fts3UpdateDocTotals&q=0&l=3434)

Depending on optimization level etc, this may turn into:

```
(1)
```

```
size = mul i32 nstat 14
```

```
chrome_sqlite3_malloc(size)
```

Three flavors of integer overflows

- Truncation bugs
 - E.g., assigning an `int64_t` into `int32_t` (3rd ex)
- Arithmetic overflow bugs
 - E.g., adding huge unsigned number (2nd ex)
- Signedness bugs
 - E.g., treating signed number as unsigned (1st ex)

Today

- Advanced modern attack techniques
 - ROP
 - Heap-based attacks
- Control flow integrity
- Integer overflow attacks

What does this all tell us?

If you're trying to build secure systems, use a memory safe language.
